|  |    |    |  |   |  |   |                              |                               |  |             |  |
| linear  | angular   | trigonal pyramidal   | tetrahedral   |   |  |   |                              |                               |  |             |  |
| 2b(i)   | weak<br>strong  | The bonds inside molecules are covalent bonds which are strong bonds. The bonds between molecules are not covalent bonds and these bonds are much easier to overcome so they are weak bonds.   |   |   |  |   |                              |                               |  |             |  |
| 2b(ii)  | One answer from:  | <table border="1" style="width: 100%; border-collapse: collapse;"> <tr> <td style="text-align: center;">Chlorine has stronger attraction for electrons</td> <td style="text-align: center;">Chlorine pulls electrons more</td> <td style="text-align: center;">Electrons not shared equally</td> </tr> <tr> <td style="text-align: center;">Hydrogen less attraction for electrons</td> <td style="text-align: center;">Hydrogen pull electrons less</td> <td style="text-align: center;">Different electronegativities</td> </tr> <tr> <td colspan="3" style="text-align: center;">Attraction for the (bonded) electrons is different</td> </tr> </table>   | Chlorine has stronger attraction for electrons                                      | Chlorine pulls electrons more   | Electrons not shared equally   | Hydrogen less attraction for electrons  | Hydrogen pull electrons less | Different electronegativities | Attraction for the (bonded) electrons is different |             |  |
| Chlorine has stronger attraction for electrons                                    | Chlorine pulls electrons more   | Electrons not shared equally   |   |   |  |   |                              |                               |  |             |  |
| Hydrogen less attraction for electrons  | Hydrogen pull electrons less  | Different electronegativities  |   |   |  |   |                              |                               |  |             |  |
| Attraction for the (bonded) electrons is different                                |   |  |   |   |  |   |                              |                               |  |             |  |
| 3a  | Diagram completed as shown:   | (concentrated) <u>hydrochloric acid</u><br><br><div style="display: flex; justify-content: space-around; align-items: center;"> <span><u>water</u></span> <span>(concentrated) <u>sulphuric acid</u></span> <span><u>chlorine</u></span> </div>  |   |   |  |   |                              |                               |  |             |  |
| 3b  |  | Each chlorine atom has 7 electrons of its own and shares an electron with another chlorine to achieve a stable full outer shell of 8 electrons.   |   |   |  |   |                              |                               |  |             |  |
| 4a  | (A substance which) burns to produce energy   | A fuel is a substance which burns to produce energy.<br>Oxygen gas is required for any substance to burn   |   |   |  |   |                              |                               |  |             |  |
| 4b(i)   | sodium hydroxide or sodium oxide  | $\text{NaH} + \text{H}_2\text{O} \longrightarrow \text{H}_2 + \text{NaOH}$ or $2\text{NaH} + \text{H}_2\text{O} \longrightarrow 2\text{H}_2 + \text{Na}_2\text{O}$   |   |   |  |   |                              |                               |  |             |  |
| 4b(ii)  | $\text{Na}^+\text{H}^-$   | Sodium is a group 1 metal so forms an sodium ion with formula $\text{Na}^+$<br>The negative ion to balance this is the hydride ion will formula $\text{H}^-$ .<br>The cross over rule would give the formula $\text{NaH}$ as both ions have a valency of one.  |   |   |  |   |                              |                               |  |             |  |
| 5a  | covalent<br>or<br>covalent molecular  | Titanium chloride is a compound containing a metal and a non-metal. This would normally form an ionic compound. However, ionic compounds are all solids at room temperature with high melting points but titanium chloride is a liquid at room temperature. Metallic bonding can be ruled out as it is a compound so (molecular) covalent is left due to the low melting and boiling points.   |   |   |  |   |                              |                               |  |             |  |

| 5b(i)   | $\text{TiCl}_4 + 4\text{Na}$ $\downarrow$ $\text{Ti} + 4\text{NaCl}$   | $\text{TiCl}_4 + 4\text{Na} \longrightarrow \text{Ti} + 4\text{NaCl}$  |                                |  |                               |   |                                       |   |   |  |  |
|---|--|--|--------------------------------|--|-------------------------------|---|---------------------------------------|---|---|--|--|
| 5b(ii)  | Titanium is less reactive than sodium  | More reactive metals will displace lower down metals from their ions/ compounds. Sodium is more reactive than titanium as the sodium metal becomes sodium ions and titanium in the compound is becoming the metal to accept the electrons released by the sodium as it becomes ions.   |                                |  |                               |   |                                       |   |   |  |  |
| 5b(iii)   | Unreactive atmosphere or no oxygen to react  | Sodium is a very reactive metal which must be kept away from oxygen or water so it would not react before the intended reaction. Argon is an unreactive gas and would prevent sodium from reacting.  |                                |  |                               |   |                                       |   |   |  |  |
